# Soldering the u-blox MAX-M10S GPS to the STEVAL-MKBOXPRO

The MovementLogger firmware reads GPS over **UART4** on MCU pins **PA0 (TX)** / **PA1 (RX)** at **38400 baud, 8N1, 3.3 V logic**. The MAX-M10S is **not** on the box — it must be wired by hand to **JP2**, the 14-pin programming connector (Samtec FTSH-107-01-L-D, 1.27 mm pitch). Full source: [GPS\\_SOLDERING.md](#).

## Tools you need

- Fine-conical-tip iron, flux, magnification (10× loupe or microscope), tweezers, steady bench.
- **30 AWG** enamelled / wire-wrap wire ( $\leq 0.5$  mm), four lengths.
- Multimeter (continuity + DC volts).
- Kapton tape + a dab of hot glue for strain relief.

## JP2 pinout — pin 1 = square pad / silk triangle

| Pin                 | Net                               | Use?                           |
|---------------------|-----------------------------------|--------------------------------|
| 1                   | 1V8 rail (JTAG ref)               | <b>NOT</b> power — 1.8 V, weak |
| 4 / 6 / 8 / 10 / 12 | SWDIO / SWCLK / SWO / JTDI / NRST | Leave alone (debug bus)        |
| 7                   | GND                               | OK for GPS GND                 |
| 11                  | GND                               | OK for GPS GND                 |
| <b>13</b>           | <b>UART4_RX (PA1)</b>             | <b>GPS TX → here</b>           |
| <b>14</b>           | <b>UART4_TX (PA0)</b>             | <b>GPS RX → here</b>           |

Pins 3, 5, 9 carry no signal — leave unconnected. **Meter-verify** pin 1 against the silkscreen triangle and continuity-check every pin before soldering — connector orientation differs between board builds.

## Wiring — note the TX/RX crossover

| GPS pin             | → | JP2 pin                       | Net (MCU)      |
|---------------------|---|-------------------------------|----------------|
| <b>TX</b> (GPS out) | → | <b>13</b>                     | UART4_RX (PA1) |
| <b>RX</b> (GPS in)  | → | <b>14</b>                     | UART4_TX (PA0) |
| <b>GND</b>          | → | 7 or 11 (meter-verified)      | GND            |
| <b>VCC 3.3 V</b>    | → | <b>JP4 3 V pin</b> (not JP2!) | Board 3 V rail |

## GPS power — 3.3 V from JP4

- JP4 is the 7-pin extension-board connector (Multicomp MC-SVT1-S07-G). Set its domain switch to **3 V** (not 1.8 V).
- Power the box and **meter the JP4 3 V pin** — must read **3.25–3.40 V** before connecting GPS VCC. Power down again before soldering VCC.
- GPS GND and box GND must be common — take GND from JP4 or a JP2 GND pin.
- No graceful shutdown: the Hall-sensor magnet cuts the whole supply rail at once (firmware F-PWR-5). The on-SD format tolerates it.

## Safety — read before the iron is hot

- **3.3 V logic only**. PA0/PA1 are **not 5 V tolerant**. A 5 V GPS breakout's TX into PA1 will destroy the MCU — level-shift or use a 3.3 V-native MAX-M10S carrier (e.g. the SparkFun breakout above).
- **Never bridge to the SWD pins** (4/6/8/10/12) — solder bridge → bricked debug access.
- Keep each pad heated  $< 2$  s. FTSH-107 pads lift if cooked.
- **Strain-relieve all four wires** with Kapton + hot glue close to JP2 — a tugged wire rips the pad off the PCB.

## Procedure

1. **Power down completely** — switch S1 off, USB unplugged, LiPo disconnected.
2. **Locate JP2** (14-pin fine-pitch header by the MCU). Identify pin 1.
3. **Continuity-check before soldering** (meter, board off): JP2 pin 13 ↔ MCU PA1, JP2 pin 14 ↔ MCU PA0, candidate GND pin ↔ battery (–). Confirm, don't assume.
4. **Pre-tin** the three JP2 pads and the wire ends with flux.
5. **Solder the data wires**: pin 13 ← GPS TX, pin 14 ← GPS RX. Then **GND**.
6. **GPS VCC last**: with the board powered, confirm 3.3 V at the JP4 3 V pin, power down again, solder the VCC wire.
7. **Inspect under magnification** for bridges — especially pin 14 to pin 12 and onto the SWD pins.
8. **Strain-relieve** all four wires (Kapton + hot glue).

## Bring-up test

1. Insert the SD card, take the box **outdoors with clear sky**, power on.
2. The firmware sends the u-blox UBX config on boot, then expects 10 Hz NMEA. First fix is typically reached within **~30–60 s cold**.
3. Confirm a fix by **any** of: a growing GpsNNN.csv on the SD card · the BLE SensorStream gps\_valid flag going set · (antenna-test build, make GPS\_ANTENNA\_BEEP=1) the buzzer beeping N times every 10 s with N = satellites.

#### No fix after several minutes outdoors? — in order of likelihood

1. **Swap the two data wires** (pin 13 ↔ pin 14). TX/RX reversed is the single most common wiring mistake and swapping is harmless to try.
2. Re-check **GND** continuity (cold/again) and that GPS VCC really is 3.3 V *at the module* under load.
3. Confirm the module is a 3.3 V part and actually powered (most MAX-M10S carriers have a power LED).
4. Give it a longer cold-start with an unobstructed sky view; indoors it will never fix.
